CS 314 Principles of Programming Languages Fall 2015

A Compiler and Optimizer for tinyL Due date: Thursday, October 22, 11:59pm

THIS IS NOT A GROUP PROJECT! You may talk about the project and possible solutions in general terms, but must not share code. In this project, you will be asked to write a recursive descent LL(1) parser and code generator for the tinyL language as discussed in class. Your compiler will generate RISC machine instructions called ILOC (Intermediate Language for Optimizing Compilers). You will also write a code optimizer that takes ILOC instructions as input and implements dead code elimination. The output of the optimizer is a sequence of ILOC instructions which produces the same results as the original input sequence. To test your generated programs, you can use a virtual machine (simulator) that can "run" your ILOC programs. The project will require you to manipulate doubly-linked lists of instructions. In order to avoid memory leaks, explicit deallocation of "dead" instructions is necessary.

This document is not a complete specification of the project. You will encounter important design and implementation issues that need to be addressed in your project solution. **Identifying these issues is part of the project**. As a result, you need to start early, allowing time for possible revisions of your solution.

1 Background

1.1 The tinyL language

tinyL is a simple expression language that allows assignments, and print as its only I/O operation. Every token is a **single** character of the input. This makes scanning rather easy, but does not allow integer constants of more than one digit, or variable names of more than one character.

```
Examples of valid tinyL programs: a=3;b=5;c=/3*ab;d=+c1;!d. a=7;b=-*+1+2a58;!b.
```

1.2 Target Architecture

The target architecture is a RISC machine with 2048 registers. All registers can only store integer values. A RISC architecture is a load/store architecture where arithmetic instructions operate on registers rather than memory operands (memory addresses). This means that for

```
<stmt_list>.
cprogram>
                ::=
<stmt_list>
                ::=
                      <stmt> <morestmts>
                     ; \langle \text{stmt\_list} \rangle \mid \epsilon
<morestmts>
                ::=
<stmt>
                     <assign> | <print>
                ::=
<assign>
                     \langle variable \rangle = \langle expr \rangle
                ::=
<print>
                ::= ! < variable >
<expr>
                     + < expr > < expr >
                ::=
                      - < expr > < expr >
                      * <expr> <expr>
                      / <expr> <expr>
                      <variable>
                      <digit>
<variable>
                ::= a | b | c | d | e | f | g | h | i | j | k | l | m | n
                     0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
<digit>
```

Figure 1: The tinyL language as specified by a context-free grammar

each access to a memory location, a load or store instruction has to be generated. Here is the machine instruction set of our RISC target architecture. You are only allowed to use these ILOC instructions. ILOC instructions are case sensitive. R_x , R_y , and R_z represent three registers.

instr. format	$\operatorname{description}$	semantics
memory instructions		
loadI $c \Rightarrow R_x$	load constant value cinto register R_x	$R_x \leftarrow c$
loadAI R_x , c \Rightarrow R_y	load value of $MEM(R_x + c)$ into R_y	$R_y \leftarrow \text{MEM}(R_x + c)$
storeAI $R_x \Rightarrow R_y$, c	store value in R_x into $MEM(R_y + c)$	$MEM(R_y + c) \leftarrow R_x$
arithmetic instructions		
add R_x , R_y \Rightarrow R_z	add contents of registers R_x and R_y , and	$R_z \leftarrow R_x + R_y$
	store result into register R_z	
sub R_x , R_y \Rightarrow R_z	subtract contents of register R_x from register	$R_z \leftarrow R_x - R_y$
	R_y , and store result into register R_z	
mult R_x , R_y \Rightarrow R_z	multiply contents of registers R_x and R_y , and	$R_z \leftarrow R_x * R_y$
	store result into register R_z	
div R_x , R_y \Rightarrow R_z	divide contents of registers R_x and R_y , and	$R_z \leftarrow R_x / R_y$
-	store result into register R_z	-
I/O instruction		
outputAI R_x , c	write value of $MEM(R_x + c)$ to standard output	print($MEM(R_x+c)$

1.3 Code Shape

Your compiler should generate code of a specific form with respect to how variables are accessed. All variables accesses use an address that consists of a **base pointer** and an **offset** relative to this base pointer. The base pointer address is stored in a special register, in our case R_0 . All memory references are therefore of the form $\text{MEM}(R_0 + \text{offset})$. This is what the instructions loadI, loadAI, storeAI and outputAI use. All addresses are **byte** addresses. Your compiler should assign the address 1024 to R_0 at the beginning of the program. For our example language, variable offsets are non-negative byte addresses. Your compiler should map variable "a" to offset 0, variable "b" to offset 4, variable "c" to offset 8, etc. Other mappings are also possible, so we are really talking about "code shape" here, which is a particular coding style.

Your compiler should generate code that does not "reuse" registers. If you assign a value to a register by a loadI, loadAI, add, sub, mult or div instruction, you will always use a fresh, i.e., new register. Your target machine has many registers, so do not worry about running out of registers. This coding style is also called the register-register model, where each computed value gets its own register. In a real compiler, an additional optimization pass maps (virtual) registers to the limited number of physical registers of a machine. This step is typically called register allocation. We do not deal with register allocation here.

1.4 Dead Code Elimination

Our tinyL language does not contain any control flow constructs (e.g.: jumps, if-then-else, while). This means that every generated instruction will be executed. However, if the execution of an operation or instruction does not contribute to the input/output behavior of the program, the instruction is considered "dead code" and therefore can be eliminated without changing the semantics of the program.

Your dead-code eliminator will take a list of RISC instructions (ILOC) as input, and generates a list of RISC instructions (ILOC) as output. The output does not contain dead code. For example, in the following code

```
loadI 1024 \Rightarrow R_0
loadI c_1 \Rightarrow R_x
loadI c_2 \Rightarrow R_y
loadI c_3 \Rightarrow R_z
add R_x, R_y \Rightarrow R_o
mult R_x, R_y \Rightarrow R_t
storeAI R_o \Rightarrow R_0, offset outputAI R_0, offset
```

the mult instruction and the third LOADI instruction can be deleted without changing the semantics of the program. Therefore, your dead-eliminator should produce the code:

```
loadI 1024 \Rightarrow R_0
loadI c_1 \Rightarrow R_x
loadI c_2 \Rightarrow R_y
add R_x, R_y \Rightarrow R_o
storeAI R_o \Rightarrow R_0, offset
outputAI R_0, offset
```

2 Project Description

The project consists of two main parts:

- 1. Complete the partially implemented recursive descent LL(1) parser that generates ILOC instructions.
- 2. Write a dead-code eliminator that recognizes and deletes redundant, i.e., dead ILOC instructions.

In addition, you are asked to write the PrintInstructionList routine. The project represents an entire programming environment consisting of a compiler, an optimizer, and a simulator (virtual machine) for ILOC. The ILOC simulator is called **sim** and will be made available to you as an executable on the ilab machines. This will allow you to check for correctness of your generated and optimized code.

2.1 Compiler

The recursive descent LL(1) parser implements a simple code generator. You should follow the main structure of the code as given to you in file Compiler.c. As given to you, the file contains code for function digit, variable, and partial code for function expr. As is, the compiler is able to generate code only for expressions that contain "+" operations on operands that are digits or the variable "f". You will need to add code in the provided stubs to generate correct RISC machine code for the entire program. Do not change the signatures of the recursive functions. Note: The left-hand and right-hand occurrences of variables are treated differently.

2.2 I/O Instruction Utility

Within the **Optimizer**, a sequence of ILOC instructions is represented as a doubly-linked list. You are asked to implement the following utility function in file **InstrUtils.c**.

```
void PrintInstructionList(FILE *outfile, Instruction *instr);
```

Function PrintInstructionList traverses the instruction list beginning with instruction "instr". The list is written into file "outfile". The implementation of this function **must be based on** the utility function

void PrintInstruction(FILE *outfile, Instruction *instr);

The implementation of the latter function is provided to you in file InstrUtils.c. This is also the file that will contain your implementation of PrintInstructionList

2.3 Dead Code Elimination Optimization

The dead code elimination optimizer expect the input file to be provided at the standard input (stdin), and will write the generated code back to standard output (stdout).

The basic algorithm identifies "crucial" instructions. The initial crucial instructions are all outputAI instructions. For all outputAI instruction, the algorithm has to detect all instructions that contribute to the value of the variable that is written out. The first instruction that needs to be found is the one that stores the value into the variable that is written out. This storeAI instruction is marked as critical and will reference a register and R_0 . There will be instructions that compute a value for this register, which also need to be marked as critical. This marking process terminates once no more instructions need to be marked as critical. If this basic algorithm is performed for all outputAI instructions, the instructions that were not marked critical can be deleted.

Instructions that are deleted as part of the optimization process have to be explicitly deallocated using the C free command in order to avoid memory leaks. You will implement your dead code eliminator pass in file Optimizer.c. All of your "helper" functions should be implemented in this file.

2.4 ILOC Simulator

The virtual machine executes ILOC program. If a outputAI <id> instruction is executed, the value of the specified memory location is written to standard output (stdout). All values are of type integer. An ILOC simulator is provided as an executable (sim). The ILOC simulator reports the overall number of executed instructions for a given input program. This allows you to assess the effectiveness of your dead code elimination optimization. You also will be able to check for correctness of your optimization pass.

3 Grading

You will submit your versions of files Optimizer.c, Compiler.c and InstrUtils.c. You may also submit an optional ReadMe file if you want to communicate something about your code to the grader. No other file should be modified, and no additional file(s) may be used. The electronic submission procedure will be posted later. Do not submit any executables or any of your test cases.

Your programs will be graded based mainly on functionality. Functionality will be verified through automatic testing on a set of syntactically correct test cases. No error handing is required. The original project distribution contains some test cases. Note that during grading we will use additional test cases not known to you in advance. The distribution also contains

executables of reference solutions for the compiler (compile.sol) and optimizer (optimize.sol), and the iloc simulator sim. A simple Makefile is also provided in the distribution for your convenience. In order to create the compiler, say make compile at the Linux prompt, which will generate the executable compile.

The provided, initial compiler is able to parse and generate code for very simple programs consisting of a single assignment statement with right-hand side expressions of only additions of numbers, followed by a single print statement. You will need to be able to accept and compile the full tinyL language.

The Makefile also contains rules to create executables of your optimizer (make optimize).

4 How To Get Started

The code for this project lives on the ilab cluster in directory:

www.cs.rutgers.edu/courses/314/classes/fall_2015_kremer/projects/proj1/students

Create your own directory on the ilab cluster, and copy the entire provided project proj1.tar to your own home directory or any other one of your directories. Say tar -xf proj1.tar to extract the project files. Make sure that the read, write, and execute permissions for groups and others are disabled (chmod go-rwx <directory_name>). IT IS CONSIDERED CHEATING IF YOU DO NOT PROTECT YOUR PROJECT FILES.

Say make compile to generate the compiler. To run the compiler on a test case "test", say ./compile test. This will generate a RISC machine program in file tinyL.out. To create your optimizer, say make optimize. The distributed version of the optimizer does not work at all, and the compiler can only handle a single example program structure consisting of a aingle assignment statement followed by a print statemet. An example test case that the provided compiler can handle is given in file tests/test-dummy.

To call your optimizer on a file that contains RISC machine code, for instance file tinyL.out, say ./optimize < tinyL.out > optimized.out. This will generate a new file optimized.out containing the output of your optimizer. The operators "<" and ">" are Linux redirection operators for standard input (stdin) and standard output (stdout), respectively. Without those, the optimizer will expect instructions to be entered on the Linux command line, and will write the output to your screen.

You may want to use valgrind for memory leak detection. We recommend to use the following flags, in this case to test the optimizer for memory leaks:

valgrind --leak-check=full --show-reachable=yes --track-origins=yes ./optimize <
tinyL.out</pre>

To run a program on the ILOC simulator, for instance tinyL.out, say ./sim tinyL.out. Finally, you can define a tinyL language interpreter on a single Linux command line as follows:

```
./compile test; ./optimize < tinyL.out > opt.out; ./sim < opt.out
```

The ";" operator allows you to specify a sequence of Linux commands on a single command line.

5 Questions

All questions regarding this project should be posted on sakai. Enjoy the project!
